Introduction

After worsening sharply during the Great Recession, the long-term fiscal outlook generally improved through 2015, due to a combination of legislative acts and lower projected growth of health care spending.[1] The same factors and the slow but steady economic recovery helped reduce short-term deficits over that period, as well.

Over the past year, though, the medium- and long-term fiscal outlooks have deteriorated. Part of this is due to legislative changes, part to changes in economic and technical factors, and a small part to changes in assumptions. This deterioration has happened without much fanfare and, even with a fall in projected interest rates working in the other direction, the estimated changes are large.

Our estimates of various fiscal measures from last September and now are summarized in Table 1. Under current policy, we project the debt-GDP ratio to be 91 percent in 2025, up from a projection of 81 percent made last September and compared to the current-year value of 75.6 percent. The projected debt-GDP ratio in 2040 has increased to 152 percent of GDP, compared to 120 percent last Fall. Our estimates of the fiscal gap —the spending or tax changes needed to bring about a fiscal balance—have also increased. The fiscal gaps through 2040 have risen by about 1.0-1.5 percent of GDP, depending on various assumptions. The permanent fiscal gap has risen by similar amounts.

The trends underlying the 10–year projections are familiar. Revenues hover at about 18 percent of GDP. Total spending is projected to rise by almost 3 percentage points of GDP—with entitlements accounting for about 1.7 percentage points of the increase and net interest for 1.9 percentage points, with discretionary spending declining by about 0.6 percent of GDP.

The projected rise in net interest payments relative to GDP reflects higher initial debt levels and an expected rise in interest rates as the economy grows. The deterioration in the budget outlook has occurred despite the fact that CBO reduced projections of future interest rates. There is considerable uncertainty over the path of interest rates, however, and much recent discussion of the notion that interest rates will remain low for an extended period of time.[2] To put this possibility in context, we examine a scenario where interest rates stay constant at current levels for the next 25 years—through 2041—rather than rising as projected by CBO. Lower interest rates, of course, reduce net interest payments, but even with flat interest rates, the fiscal situation is headed in the wrong direction. The current policy projections with flat interest rates show the debt-GDP ratio rising to 110 by 2041. Even with low interest rates, the fiscal gap just to maintain the current debt-GDP ratio in 2041 is 1.8 percent. To reduce the ratio to its 1957-2007 average of 36 percent by 2041 would require spending cuts or tax increases of 3.6 percent of GDP. Thus, while low interest rates may reduce net interest payments in the near term, they do not put federal debt on a sustainable path.

The 10-Year Budget Outlook

Assumptions

We construct 10-year projections by starting with the CBO's January 2016 current-law baseline (CBO 2016) and making a series of adjustments. These adjustments are admittedly judgmental. In our view, they provide a better picture of what constitutes current policy than do the CBO current-law projections, which in many instances reflect budget conventions or assumptions that the CBO is required to make by law.

On the tax side, we assume that all temporary tax cut or tax delay provisions are made permanent. This includes 50 percent expensing of equipment and property for business investment. It also includes the permanent repeal of certain healthcare taxes in the Affordable Care Act, including the medical device excise tax and the tax on high-premium insurance (commonly known as the "Cadillac Tax"). The implementation of these taxes was recently postponed by two years in the Protecting Americans from Tax Hikes Act of 2015.

On the spending side, CBO sets discretionary spending through 2021 at the levels created by the recent discretionary spending caps and sequestration procedures (as imposed in the Budget Control Act of 2011 and modified by the Bipartisan Budget Act of 2013) and then allows them to rise with inflation. In contrast, we allow defense spending to rise with inflation, starting in 2017, so that real defense expenditures remain constant at 2016 levels. We allow non-defense discretionary spending to rise with the rate of inflation and the rate of population growth, so that real, per-capita spending remains constant at 2016 levels, a rough approximation of a budget that maintains current services per person.[3]

[1] Auerbach and Gale (2009, 2015).
[2] See Elmendorf and Sheiner (2016).

[3] Our most recent prior estimates did not adjust non-defense discretionary spending for population growth. We make the adjustment for population growth in the current estimates because of a sense that the Bipartisan Budget Act of 2015 indicates a stronger desire for discretionary spending, on both sides of the aisle, than the current caps suggest. Our most recent previous estimates include an adjustment for a phase-down of military overseas contingency operations spending due to projected troop withdrawals abroad. We do not make this adjustment in the current projections, as security needs appear to have increased over the past year. CBO does not include an OCO adjustment this year either.

Basic Results

Deficit-GDP and debt-GDP ratios are reported in Figures 1 and 2 and in Appendix Table 1. The deficit rises from 2.9 percent of GDP in 2016 to 4.9 percent of GDP in 2026 under the current law baseline and 6.1 percent of GDP under our view of current policy.[4]

The underlying economic projection behind these estimates assumes that the economy remains close to full employment throughout the second half of the projection period. Figure 1 shows that the cyclically-adjusted deficit (i.e., the deficit with automatic stabilizers removed) rises to 5.9 percent of GDP by 2026. As noted above, this would the highest full-employment deficit, other than during the Great Recession, in the post-War period.

Figure 1 also shows that the primary deficit rises over time. As discussed below, there is some uncertainty over the path that interest rates, and hence net interest payments, will follow. The rising primary deficit shows that there is a growing fiscal shortfall under any interest rate scenario.

As shown in Figure 2, under current policy, the debt-GDP ratio remains near the 2016 value of 76 percent of GDP until 2018, after which it starts rising steadily to reach 93.6 percent by 2026 under current policy. (The ratio rises to 86.1 percent under current law).

Given this basic summary, several aspects of the 10-year budget outlook stand out:

The current debt-GDP ratio is high relative to U.S. historical norms. At 75.6 percent of GDP, the debt-GDP ratio at the end of 2016 is the highest in U.S. history other than during a seven-year period around World War II. From 1957 to 2007, the ratio never exceeded 50 percent and averaged just 36 percent of GDP. In 2007, before the financial crisis and the Great Recession, the ratio was 35 percent.

The debt-GDP ratio is projected to rise over the decade, whereas in previous high-debt episodes it fell rapidly. The debt-GDP ratio rises by 17 percentage points from 2018 to 2026. This increase occurs despite the projection of a near full-employment economy during this period, hinting at an unsustainable fiscal situation and the need for longer-term analysis. It also highlights the difference between the current situation and previous high-debt episodes in U.S. history.

In such episodes—the Civil War, World War I, and World War II—the debt-GDP ratio was cut in half roughly 10-15 years after the war ended.

Total spending is projected to rise over the decade, with the composition shifting significantly. Total spending under current policy rises from 21.2 percent of GDP in 2016 to 24.0 percent by 2026 (Figure 3). This compares to a historical average of 20.0 percent for 1962 to 2015. Net interest payments rise from 1.4 percent of GDP in 2016 to 3.2 percent in 2026. The CBO assumes that interest rates will rise significantly as the economy grows.[5] Below, we report budget outlook estimates with lower interest rates.

Non-interest outlays rise by about 1 percent of GDP, with increases in mandatory spending offset in part by declines in discretionary spending. Non-interest spending rises from 19.8 percent of GDP in 2016 to 20.7 percent by 2026. The average value from 1962 to 2015 was 18.1 percent.

Figure 4 shows the projected composition of spending. Discretionary spending falls from 6.5 percent of GDP in 2016 to 5.8 percent in 2026. Within that category, defense spending declines from 3.2 percent in 2016 to 2.8 percent in 2026, while non-defense discretionary spending falls from 3.3 percent of GDP in 2016 to 3.0 percent of GDP in 2026. All of these shares are low relative to historical figures. Since 1962, the lowest discretionary spending share of GDP occurred in 1999, at 6.0 percent. The lowest share for defense spending was 2.9 percent of GDP in 1999-2001. The lowest nondefense discretionary spending share of GDP was 3.1 percent in 1998-1999.

Under current policy, mandatory spending is projected to rise from 13.3 percent of GDP in 2016 to 15.0 percent in 2026. Spending on Social Security rises by about 1 percent of GDP, net Medicare spending rises by 0.7 percent of GDP and Medicaid benefits, CHIP, and exchange subsidies rise by 0.3 percent of GDP. Other entitlement spending will decline by 0.3 percent of GDP.

Revenues are projected to decline as a share of GDP, but remain above historical average levels. Revenues are projected to fall from 18.3 percent of GDP in 2016 to 17.9 percent of GDP in 2026. Revenues averaged 17.4 percent of GDP from 1962 to 2015. Notably, income tax revenues are projected to rise to 9.2 percent of GDP by 2026 under current policy. The only years in which the income tax has ever raised at least 9 percent of GDP in revenue were 1944 (at the height of World War II), 1981-82 (before the Reagan tax cuts took full effect), and 1998-2001 (helped by a strong economy and the tech stock bubble, and leading to the Bush tax cuts in 2001 and 2003). Thus, the forecast deficits already incorporate a reasonably strong revenue picture.

[4] CBO (2016, page 14) explains that the deficit for fiscal year 2016 will be about $43 billion higher than would otherwise be expected because October 1, 2016 (the beginning of fiscal year 2017) falls on a weekend, thus pushing some payments to the end of September. Similar issues reduce the deficits in 2018 and 2024 and raise it in 2022.

[5] The three-month Treasury bill rate rises to 2.3 percent in 2018 compared to 0.5 percent in 2016, according to CBO's January 2016 economic projections (CBO 2016). The 10-year Treasury note rate rises to 3.8 percent in 2018 compared to 2.6 percent in 2016. Various measures of the inflation rate such as the Consumer Price Index are expected to rise around 2 percentage points over the same period; the remainder of the increases represents changes in real interest rates.

Sensitivity Analysis: The effects of low interest rates

As noted above, CBO's projections assume rising interest rates over time. Those projections, however, have been revised downward repeatedly over the last several years. More generally, low interest rates on government debt have proven more persistent than most observers would have guessed at the beginning of the Great Recession. To test the effect of interest rates assumptions on the budget outlook, we adopt what we believe is an extreme assumption – namely, that nominal interest rates stay constant at their implied 2016 value (1.94 percent) through 2026.[6] Under this scenario, still assuming current policy for other tax and spending programs, we find that in 2026, compared to using CBO interest rate assumptions:

- Net interest payments are 1.5 percent of GDP by 2026, instead of 3.2 percent;
- The deficit rises to 4.4 percent of GDP, instead of 6.1 percent;
- The full-employment deficit rises to 4.2 percent, compared to 5.9 percent;
- Debt rises to 81.1 percent of GDP compared to 93.6 percent.

Thus, lower interest rates improve the 10-year budget outlook, but the debt-GDP ratio is still projected to rise even if interest rates remain at the current level for the next 10 years.

Trust Funds

The federal government runs several trust funds, most notably for Social Security (Old Age and Survivors Insurance), Disability, Medicare (two separate funds), civilian and military retirement, and transportation spending. All of the projections highlighted above integrate the trust funds into the overall budget. These projections also assume that scheduled benefit payments will be made even if trust funds run their balances to zero. However, many of the trust funds are not legally allowed to pay out benefits that draw their balances below zero.

This is not just an academic concern. This trust-fund constraint was one of the proximate causes of Social Security reform in 1983; the trust fund literally had almost run out of money, an eventuality that would have required cuts in promised benefits so that they would not exceed revenues coming in. Despite recent legislation, the highway and mass transit trust fund is scheduled to have to make cuts starting in the middle of this year. Likewise, the disability (DI) trust fund is scheduled to have to make forced adjustments by 2022. This is actually an improvement over prior estimates, which placed the DI trust fund adjustments in late 2016. This is the result of a shift in payroll tax funds from OASI to DI in the 2015 budget deal. The Medicare Part A (hospital insurance) fund appears, according to the 2015 Trustees Report, likely to hit a similar constraint shortly after 2030 (Board of Trustees 2015).

Each of these dates may force at least limited fiscal action. In each case, legislators will be forced to override the rules regarding trust funds, make inter-fund transfers, reduce benefits, or raise taxes. In contrast, Social Security (OASI) does not have cash flow issues for a couple of decades and Medicare parts B (Supplementary Medical Insurance) and D (Drug Insurance) do not have the constraint that spending can only be financed by trust fund payments.

Although low trust balances may require action, low balances and actions to address them relate to individual programs and the nature of their funding sources, and provide an incomplete picture of the federal government's overall fiscal position over the longer term, an issue to which we now turn our attention.

The Long-Term Budget Outlook

Assumptions

For our long-term model, we assume that most categories of spending and revenues remain constant at their baseline 2026 share of GDP in subsequent years. Assuming constant shares of GDP, however, would be seriously misleading for the major entitlement programs and their associated sources of funding. For the Medicare and OASDI programs, in our base case we project all elements of spending and dedicated revenues (payroll taxes, income taxes on benefits, premiums and contributions from states) using the intermediate projections in the 2015 Trustees reports.[7] Social Security spending, Medicare spending, and payroll taxes follow the growth rates assumed in the Trustees' projections of the ratios of taxes and spending to GDP for the period 2027–2090 for OASDI and Medicare, assuming that these ratios are constant at their terminal values thereafter. For Medicaid, CHIP, and exchange subsidies, we use growth rates implied by CBO's most recent long-term projections (CBO 2015) through 2090 and assume that spending as a share of GDP is constant thereafter.

In our base case, we use interest rate and growth assumptions implied in CBO (2015). The interest rate is obtained by dividing net interest payments in a given year by public debt in the previous year. Over the 2027-2091

[6] This interest rate is calculated by dividing the estimated net interest payments in 2016 from CBO (2016) by the debt at the end of 2015. CBO (2016).

[7] Details of these computations are available from the authors upon request. The 2015 Medicare Trustees Report is at https://www.cms.gov/Research-Statistics-Data-and-Systems/Statistics-Trends-and-Reports/ReportsTrustFunds/Downloads/TR2015.pdf. The 2015 OASDI Trustees Report is at http://www.ssa.gov/oact/tr/2015/tr2015.pdf.

period, the average nominal economic growth rate is 4.3 percent and the average nominal interest rate is 4.4 percent.[8] For years after 2090, we use the 2090 values of 4.3 percent for the growth rate and 4.4 percent for the interest rate.

By assuming that many categories of tax revenues and spending remain constant relative to GDP, we are not simply projecting based on current law, but instead we are assuming that policymakers will make a number of future policy changes, including a continual series of tax cuts, discretionary spending increases, and adjustments to keep health spending from growing too quickly. If current-law tax parameters were extended forward, income taxes would rise as a share of GDP (due to bracket creep and rising withdrawals from retirement plans). If discretionary spending were held constant in real terms, it would fall continually as a share of GDP. Our projection also assumes that a wealthier and more populous society will want to maintain discretionary spending as a share of GDP. We provide sensitivity estimates below.[9]

We provide three projections of Medicare spending. As noted, our base case projections come from the intermediate projections of the Medicare Trustees, which have for many years incorporated the assumption that Medicare growth will eventually slow in the future. Starting in the 2010 report, however, the Trustees' official medical projections have assumed a much stronger slowdown, as a consequence of provisions in the ACA. These assumptions, though they may be consistent with the impact of the bill's provisions should they remain in force over the long term, are not adopted by other forecasters, who have a more pessimistic outlook. For example, the Medicare Actuary has, since 2010, released a separate set of projections (CMS Office of the Actuary 2015) showing smaller (although still positive) reductions in spending, which is the source of our second projection. The third projection is the alternative Medicare scenario in CBO's Long-Term Budget Outlook (2015), which projects a still more pessimistic path for Medicare spending. The three scenarios generate fairly similar trends for next 25 years—by 2040, the estimates differ by a maximum of 0.6 percent of GDP. Over longer periods, however, the projections diverge significantly; by 2090, the estimates range from 5.0 percent of GDP under the Medicare Trustees' assumptions to 10.2 percent under CBO's.

We assume that all remaining revenue and expenditure components except net interest remain constant as a share of GDP after 2090.

Debt Projections

Figure 5 shows the debt trajectory under current policy, using the Medicare Trustees projections for health care (i.e., the lowest of the three health options). The debt-to-GDP ratio rises from 93.6 percent in 2026, hits 100 percent in 2028, exceeds the previous all-time high of 106 percent in 2030, and rises to 156 percent by 2041—25 years from now.

The figure also shows the effect of low interest rates. Specifically, in this scenario we hold interest rates constant at current levels through 2041. Under current policy with low interest rates, the debt-GDP ratio rises to 110 percent by 2041.

After 2041, we assume that interest rates revert to the estimates in the long-term outlook described above. By 2066, the debt-GDP rises to 278 percent of GDP under the current policy scenario, and 232 percent under current policy with low interest rates through 2041. The debt-GDP ratio continues to rise after 2066 in both scenarios.

The Fiscal Gap

The fiscal gap is an accounting measure that is intended to reflect the long-term budgetary status of the government (Auerbach 1994).[10] The fiscal gap answers the question: if you want to start a policy change in a given year and reach a given debt-GDP target in a given future year, what is the size of the annual, constant-share-of-GDP increase in taxes and/or reductions in non-interest expenditures (or combination of the two) that would be required? For example, one might ask what immediate and constant policy change would be needed to obtain the same debt-GDP in 2090 as exists today. [11] Or one might ask, if we wanted the debt-GDP ratio to return to its 1957-2007 average of 36 percent by 2041, what constant-share-of-GDP change would be required starting in 2021?

The first row of Table 2 shows fiscal gap estimates using the Medicare trustee projections for health care. We show fiscal gaps for three different horizons, assuming the policy changes begin in 2016, and aiming for the same debt-GDP ratio in the terminal year (73.6 percent of

[8] The implied interest and growth rates vary somewhat on an annual basis due to rounding. We also considered an alternative (not shown in the tables below) with higher long-run interest rates and a larger gap between the two, by assuming that economic growth occurred at the rate projected by the Social Security trustees (which averages 4.44 percent after 2026, just slightly above that in our baseline) and using the Trustees' projected interest rates (which averages 5.57 percent) to calculate net interest payments. This yields slightly higher fiscal gaps than those presented below in Table 1 through 2041 and 2091, and lower or higher gaps over the indefinite period depending on the starting date of consolidation.

[9] Kamin (2012) and Kogan et al. (2013) provide additional perspective on these assumptions.

[10] Auerbach et al. (2003) discuss the relationship between the fiscal gap, generational accounting, accrual accounting and other ways of accounting for government.

[11] Over an infinite planning horizon, this requirement is equivalent to assuming that the debt-to-GDP ratio does not explode (Auerbach 1994, 1997). For the current value of the national debt, we use publicly-held debt. An alternative might be to subtract government financial assets from this debt measure, but the impact on our long-term calculations would be small (reducing the fiscal gaps by less than 0.1 percent of GDP).

GDP) as existed at the end of 2015. The estimated gap through 2041 is 2.98 percent of GDP. This implies that an immediate and permanent increase in taxes or cut in spending of about $555 billion per year in current terms would be needed to achieve the current debt-GDP ratio in 2041.

The fiscal gap is larger if the time horizon is extended, since the budget is projected to be running substantial deficits in more distant future years. If the horizon is extended through 2091, the fiscal gap rises to 4.45 percent of GDP. If it is extended indefinitely, the gap rises to 5.76 percent of GDP.

The second and third rows of the table show that the choice of health care scenario has a significant and varying impact on the estimated fiscal gaps. Through 2041, the differences in the fiscal gaps implied by the different health care scenarios are small. Over longer periods, however, the differences are much larger. Using the CMS actuaries' projections instead of the Medicare Trustees' projections raises the fiscal gap by about 1.2 percent of GDP through 2091 and 3.0 percent of GDP on a permanent basis. Using the CBO Medicare projections raises the gap by an additional 0.8 percent of GDP through 2091 and an additional 1.9 percent of GDP over the infinite horizon.

The rest of Table 2 displays a variety of sensitivity analyses concerning policy assumptions. Assuming that outlays for discretionary and other mandatory spending stays constant in real, per capita terms after 2026 (instead of a constant share of GDP) reduces the fiscal gap by about 0.4 percent of GDP through 2041, 2.3 percent of GDP through 2091, and about 4.8 percent of GDP on a permanent basis.

Assuming that tax revenues follow current law after 2026 (instead of remaining a constant share of GDP) reduces the fiscal gap by 0.3 percent of GDP through 2041, 2.4 percent of GDP through 2091, and 6.3 percent of GDP on a permanent basis.

Table 3 shows fiscal gaps under different combinations of debt targets, dates for reaching the target, and dates for implementing the policy changes. We employ three debt targets—73.6 percent, the ratio of debt-to-GDP at the end of 2015; 60 percent, a ratio proposed by several commissions, including Bowles-Simpson (National Commission on Fiscal Responsibility and Reform 2010) and Domenici-Rivlin (Debt Reduction Task Force 2010), and 36 percent (representing simultaneously (a) the average from 1957-2007, before the Great Recession, (b) roughly the value in 2007 as the financial crisis and Great Recession hit, and (c) a target that cuts the current debt-GDP ratio roughly in half). We look at both 25-year and 75-year target dates for reaching the new debt-GDP level.

We employ two start dates for policy: current (i.e. 2016) and 2021, the latter reflecting the reality of political deadlock, the undesirability of austerity policies in a weak economy, and the possibility of implementation delays. The first line of Table 2 replicates the fiscal gap calculations through 2041 and 2091 shown in the top row of Table 1, for obtaining a 75.6 percent debt-GDP ratio in the target year, with the policy starting in 2016.

The main message of Table 3 is that it will be quite difficult to return to historical levels of the debt-GDP ratio anytime soon. To get the debt-GDP ratio in 2041 down to 36 percent would require immediate and permanent spending cuts or tax increases of 4.4 percent of GDP. This would require a 24 percent increase in current tax revenues or a 22 percent cut in non-interest spending.

The problem is even harder if the policy does not take effect until 2021. Just maintaining the 2041 debt-GDP ratio at its current level would require annual cuts of 3.5 percent of GDP starting in 2021. Reducing the debt-GDP ratio to 60 percent in 2041 would require cuts 4.0 percent of GDP beginning in 2021. To get the debt-GDP ratio down to 36 percent by 2041 would require deficit reduction of 5.2 percent of GDP per year starting in 2021. To achieve that ratio in 2091 would (by coincidence) also require cuts of 5.2 percent of GDP starting in 2021.

Holding interest rates at their implied 2016 rate through 2041 does not paint that much of a better picture, either. Even under this scenario, it would require immediate spending cuts or tax increases of 1.8 percent of GDP just to maintain the current debt ratio through 2041. If the policy were delayed until 2021, the required policy adjustment would be 2.0 percent in order to maintain the current debt-GDP ratio in 2041 and 4.2 percent of GDP in order to reduce the debt-GDP ratio to 36 percent by then. The longer policy makers wait to make the adjustments, the larger the eventual adjustments will have to be.

Uncertainty and Its Implications

Budget projections are not written in stone. Clearly, they should be taken with a grain of salt – perhaps a bushel. They are, at best, the educated guesses of informed people, and the role of uncertainty in budget projections should not be underestimated, particularly as the time horizon lengthens. In the past, budget projections by the CBO and others (including us) have proven to be too optimistic in some instances and too pessimistic at others.

Major sources of uncertainty—noted in the analysis above—include the behavior of interest rates, trends in health care spending, shifts in demographics, and, of course, the choices of policy makers. In each case, the uncertainty can create significant changes in outcomes because errors tend to compound over time. Nevertheless, although there is substantial uncertainty regarding the outlook, reasonable estimates imply an unsustainable fiscal path that will generate significant problems if not addressed.

How should the presence of that uncertainty affect when and how we make policy changes? One argument is that we should wait; after all, the fiscal problem could go away. But, for several reasons, ignoring the problem is unlikely to be an optimal strategy.

First, regardless of whether the long term turns out to be somewhat better or worse than predicted, there is *already* a debt problem. The debt-GDP ratio has already doubled, to more than 70 percent. The future is already here. There are benefits to getting the deficit under control – including economic growth and fiscal flexibility – regardless of whether the long-term problem turns out to be as bad as mainstream projections suggest. If carrying high debt were costless economically and politically, many more countries would have done so before the Great Recession. In fact, very few had net debt to GDP ratios above 70 percent.

Second, purely as a matter of arithmetic, the longer we wait, the larger and more disruptive the eventual policy solutions will need to be, barring a marked improvement in the fiscal picture. Policy makers certainly may not have wanted to reduce spending or raise taxes during the relatively weak economic recovery starting in 2009, but that is different from not planning ahead. Note that addressing the issue now does not necessarily mean cutting back on *current* expenditures or raising *current* taxes substantially or even at all; rather, it may involve addressing future spending and revenue flows now, in a credible manner.

Third, uncertainty can cut both ways and the greater the uncertainty the more we should want to address at least part of the problem now. The problem could turn out to be worse – rather than better – than expected, in which case delay in dealing with the problem would make solutions even more difficult politically and even more wrenching economically. If people are risk-averse, the existence of uncertainty should normally elicit precautionary behavior—essentially "buying insurance" against a really bad long-term outcome by reducing the potential severity of the problem – through enactment of at least partial solutions to the budget problem right away.[12]

Lastly, although the point may seem obvious, it is useful to emphasize that even if the main driver of long-term fiscal imbalances is the growth of entitlement benefits, this does not mean that the only solutions are some combination of benefit cuts now and benefit cuts in the future. For example, when budget surpluses began to emerge in the late 1990s, President Clinton devised a plan to use the funds to "Save Social Security First." Without judging the merits of that particular plan, our point is that Clinton recognized that social security faced long-term shortfalls and, rather than ignoring those shortfalls, aimed to address the problem in a way that went beyond simply cutting benefits. A more general point is that addressing entitlement funding imbalances can be justified precisely *because* one wants to preserve and enhance the programs, not just because one might want to reduce the size of the programs. Likewise, addressing these imbalances may involve reforming the structure of spending, raising or restructuring revenues, or creating new programs, as well as simply cutting existing benefits.

Conclusions

Although current deficits are reasonably low, the medium- and long-term fiscal outlooks have deteriorated in the past year, due largely to legislative actions (and their implications for future policy) and changes in economic projections. Even under a low interest rate scenario, the long-term budget outlook is unsustainable. Moreover, the nation already carries a debt load that is twice as large as its historical average as a share of GDP and that makes evolution of the debt-GDP ratio much more sensitive to interest rates.

The necessary adjustments will be large relative to those adopted under recent legislation. Moreover, the most optimistic long-run projections already incorporate the effects of success at "bending the curve" of health care cost growth, so further measures will clearly be needed.[13] These changes, however, relate to the medium- and long-term deficits, not the short-term deficit.

[12] This argument is discussed at greater length in Auerbach (2014).

[13] These projections must be viewed as even more optimistic than before the recent legislation to delay implementation of the Cadillac tax, as they have not been updated to reflect the faster growth in health care spending that may be a consequence of delay (or repeal) of this measure to restrain cost growth.

Table 1
Projection Comparisons Between 2015 and 2016

(Percent of GDP)

Current Law	**September 2015**	**February 2016**
2025 Deficit	3.7	4.6
2025 Full Employment Deficit	3.5	4.4
2025 Debt	76.9	84.3
2040 Debt	109.2	130.9
Fiscal Gap		
To obtain current debt-GDP ratio in 2040, starting in 2020	1.6	2.5
To cut debt-GDP ratio to 36% in 2040, starting in 2020	3.4	4.2
To obtain the current debt-GDP ratio permanently	3.8	4.9
Current Policy		
2025 Deficit	4.2	5.7
2025 Full Employment Deficit	4.0	5.5
2025 Debt	81.3	91.0
2040 Debt	119.9	151.5
Fiscal Gap		
To obtain current debt-GDP ratio in 2040, starting in 2020	2.0	3.4
To cut the debt-GDP ratio to 36% by 2040, starting in 2020	3.8	5.1
To obtain the current debt-GDP ratio permanently	4.2	5.8

Table 2
Fiscal Gaps

(Percent of GDP)

	Through 2041	Through 2091	Permanent
Health Spending Assumptions			
Medicare Trustees	2.98	4.45	5.76
CMS Actuary	3.10	5.65	8.80
CBO Alternative Scenario	3.16	6.43	10.67
Alternative Policy Options (Incremental Effects)[1]			
Discretionary and Other Mandatory Outlays Grow at Real Per Capita Rates (after 2026)	-0.37	-2.34	-4.80
Revenues Grow with Bracket Creep and Retirement Withdrawals (after 2026)	-0.26	-2.41	-6.31

Source: Authors' calculations

[1]The Alternative Policy Options are additive to the above fiscal gaps as they do not interact with the different health scenarios or each other.

Table 3
Fiscal Gap Calculations for Various Start Dates, Target Dates and Target Ratios

(Percent of GDP)

	Current Policy		Low Interest Rate Scenario	
	Through 2041	**Through 2091**	**Through 2041**	**Through 2091**
Start Date: 2016				
Debt Target				
Current	2.98	4.45	1.76	4.23
60	3.42	4.60	2.33	4.39
36	4.37	4.93	3.58	4.75
Start Date: 2021				
Debt Target				
Current	3.50	4.71	2.03	4.41
60	4.04	4.87	2.70	4.58
36	5.22	5.22	4.18	4.95
